
running example $H(x) = \sin(2x)\,(Z_0 Z_1 + X_0 + X_1)$, $x = 0.7$, $T = 5.0$ μs, 2 qubits — ONE branch of each strategy, as emitted on the six physical channels
Nyquist mode n=0, shift s=0.2067 (K=1.210); machine residual 9.0e-05 (source) / 8.8e-05 (shifted). A gradient needs many branches either way — PSR spends them on a τ quadrature, NSR on drawn shifts; how many is Fig. 10's question, not this figure's.
PSR (kick)
one branch = 119.83 μs; 95% of it transport + gate
NSR (waveform shift)
one branch = 5.00 μs = T; 24× shorter, same geometry
transport AOD x
atom position (μm)
transport AOD y
addressing: detuning
addressing: Rabi
dressing AOM
gate AOM
silent
COMB: one tone per atom, 10 MHz apart ⇒ $|A|$ beats at ~100 ns
time within one branch (μs) — axis spans 0–119.8
time within one branch (μs) — axis spans 0–5
PSR
NSR
transport + gate 114.1 μs
5.00 μs — one PSR branch buys 24 of these
the columns above are on their own axes; this strip is the common one (μs)
gate AOM: measured shape, 696 ns ($|A|$ over the resolved carrier)
ns after gate start
addressing Rabi comb: the shift is an amplitude change
identical carrier and phase; amplitude ×0.985
PSR (source amplitude)
NSR (shifted)
ns from start
